We report a case of a 45-year-old man with a complaint of both leg weakness and hypoesthesia. Radiological evaluation revealed an osteolytic lesion of the ninth thoracic vertebra. The patient underwent posterior corpectomy with total excision of the tumor, mesh cage insertion with posterior screw fixation and subsequent radiotherapy. Histology confirmed the diagnosis of Langerhans cell histiocytosis (LCH). This case report presents the diagnostic work-up, histopathological evaluation, and the treatment procedures of rare LCH in the thoracic spine.

Key Words: Langerhans cell histiocytosis, Thoracic spine, Adults

INTRODUCTION

Langerhans cell histiocytosis (LCH) is a clonal proliferation of Langerhans cells occurring as an isolated lesion or as part of a systemic (multifocal) proliferation¹⁰. LCH is a rare disorder characterized by an excessive proliferation of pathologic Langerhans cells. The disease varies widely in clinical presentation from localized involvement of a single bone to a widely disseminated life-threatening disease⁷. Since the cell of origin in this disease is now clearly defined, the term LCH should substitute all the previously used terms, such as histiocytosis X, eosinophilic granuloma, Hand-Schuller-Christian disease and Letterer-Siwe disease¹. We report a case of 45-year-old man diagnosed as LCH of the thoracic spine with the diagnostic work-up, histopathological evaluation and treatment procedures.

CASE REPORT

A 45-year-old man presented with 1 month of left flank pain, 10 days of hypoesthesia and weakness at both lower extremity. He also complained that he had difficulty going up the stairs and keeping his balance. There was no history of systemic illness and family history. On examination, he had elevated deep tendon reflex of right knee, motor weakness of both lower extremity (grade 4) and hypoesthesia below T10 dermatome. His body temperature was normal and result of blood tests, such as white blood cell (WBC), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), were all slightly increased (WBC, 11.9 K/ μ L [4 K/ μ L–10 K/ μ L]; ESR,

10 mm/hr [0–28 mm/hr]; CRP, 1.18 mg/dL [0–0.3 mg/dL]).

Computed tomography (CT) scans revealed fracture of T8, T9 vertebral body by bone tumor (Fig. 1). Magnetic resonance imaging (MRI) showed pathologic fracture of T9 vertebral body by bone tumor, T8–10 myelopathy and cord compression (Fig. 2). Whole body PET showed focal hypermetabolic lesion around the T9 spine area. There was no other abnormal finding. So we assumed that the lesion is a primary bone tumor.

Due to motor weakness and radiologic finding, the patient underwent T9 corpectomy and mesh cage insertion with T8–10 posterior screw fixation (Figs. 3, 4). Pathological examination confirmed a diagnosis of LCH. There was a positive immunohistochemical reaction of CD1a and S-100 protein (Fig. 5). Then he underwent radiotherapy at T8–10 spine (200 cGy, 10 times). After the operation, the patient recovered both leg weakness and hypoesthesia. The patient gave a written informed consent and was enrolled in the study. Now he has been followed for almost 6 years without any recurrence.

DISCUSSION

LCH is a rare disease with a rather unpredictable course since it can spontaneously resolve or progress to a disseminated form, compromising vital functions with occasionally fatal consequences. The etiology of LCH remains unknown, and inconsistencies in the published literature also reflect a lack of understanding about the cause of the disease. LCH is mostly seen in children and adolescents. The peak incidence is between ages 5 and 10 years in about 80%

Fig. 2. Magnetic resonance imaging showed pathologic fracture of T9 vertebral body by bone tumor, T8-10 myelopathy and cord compression. Gadolinium enhanced sagittal image (A), T1-weighted (B), T2-weighted (C), and Gadolinium enhanced axial image (D).

of the cases^{3,6}. The most frequently reported anatomic sites are those in the skull (26%), vertebra (7%), ribs (12%), upper and lower jaw (9%), and bones of extremities (11%)^{2,8}. In the spine, LCH mainly involves the vertebral bodies, with a predilection for the thoracic spine (54%) followed by the lumbar (35%) and cervical spine (11%)^{5,6}. The present case was a solitary osseous lesion with no evidence of systemic symptoms and within T9 body.

Single or multiple sharply-circumscribed osteolytic lesions can be seen by the radiological studies. The most common radiographic features in spinal LCH in both groups were lytic lesions of the vertebra, which usually led to vertebral collapse. The typical sign of vertebral collapse was a flattening of the vertebral body (vertebra plana)³. In our case, conventional X-ray, CT and

Fig. 3. (A, B) Immediate postoperative X-ray showed T9 corpectomy and mesh cage insertion with T8-10 posterior screw fixation.

Fig. 4. (A, B) After 3 years of follow-up, magnetic resonance imaging showed completely disappeared Langerhans cell histiocytosis.

Fig. 5. Pathological examination confirmed a diagnosis of Langerhans cell histiocytosis. There was a positive immunohistochemical reaction of CD1a ($\times 400$) (A) and S-100 protein ($\times 400$) (B).

MRI scans were performed and an osteolytic destruction of the T9 vertebra was detected during the work-up.

There is a variety of treatment strategies mentioned in the literature. Many studies have shown excellent healing and resolution of LCH using a variety of treatment including bracing, surgery, chemotherapy, radiation therapy, and even no therapy

for its excellent prognosis⁴⁾. Intralesional corticosteroid injection⁹⁾ or operative treatment with curettage, lesionectomy, corpectomy have been described^{3,9)}. Postoperative chemotherapy or radiotherapy are also mentioned in the literature^{3,9)}. Spontaneous regression of the bone lesion after 6 months has also been reported^{1,8)}.

In case of solitary spinal lesion with neurological impairment, surgical treatment is recommended. But the role of postoperative radiotherapy is still controversial⁸⁾. In our case, we performed corpectomy and mesh cage insertion with posterior fixation. Then the patient underwent radiotherapy. After 6-year follow-up, no evidence of recurrence or neurological deficits has been identified.

CONCLUSION

We report our experience with a very rare case of LCH of the thoracic spine in 45-year-old man. The patient had a solitary spinal lesion and underwent surgical treatment and radiotherapy successfully.
